| Horn et al. 2014 (CT) Horn et al. 2015 (Cost-Effectivenes Studie) | A) = 76  
B) = 688 | Persönlichkeitsstörungen | A) inpatient psychotherapy based on transactional analysis (STIP-TA)  
B) other psychotherapies (OP) | CT: The primary outcome measure was general psychiatric symptomatology; secondary outcomes were psychosocial functioning and quality of life. In 67 pairs of patients, both STIP-TA and OP showed large symptomatic and functional improvements. However, STIP-TA patients showed more symptomatic improvement at all time points compared to OP patients. At 36 months, 68% of STIP-TA patients were symptomatically recovered compared to 48% of OP patients. STIP-TA outperformed OP in terms of improvements in general psychiatric symptomatology and quality of life. Superiority of STIP-TA was most pronounced at 12-month follow-up, but remained intact over the course of the 3-year follow-up.  
Cost-Effectiveness: Mean three year costs were €59,834 for STIP-TA and €69,337 for OP, a difference of €-9,503 (95% CI -32,561 to 15,726). Costs per quality adjusted life years (QALYs) were 2.29 for STIP-TA and 2.05 for OP, a difference of .24 (95% CI .05 to .44). The STIP-TA intervention was dominant, thus less costly and more effective than OP. Sensitivity analyses displayed similar results. |
| Kreuzer et al. 2012 | 36 | Tinnitus | A) Mindfulness and body-psychotherapy based group treatment of chronic tinnitus  
B) Waitlist | ANOVA testing for the primary outcome showed a significant interaction effect time by group (F = 7.4; df = 1.33; p = 0.010). Post hoc t-tests indicated an amelioration of TQ scores from baseline to week 9 in both groups (intervention group: t = 6.2; df = 17; p < 0.001; control group: t = 2.5; df = 16; p = 0.023), but the intervention group improved more than the control group. Groups differed at week 7 and 9, but not at week 24 as far as the TQ score was concerned. |
| Shashi et al. 1999 | 10 | Emotionale Störungen des Kindesalters | A) Non-directive play therapy + family counseling  
B) Family counseling | The results reveal statistically significant reduction of symptoms between pre- and post-therapy assessments in the study group but not in the control group |
| Szigethy et al. 2014 | 178 | Psychische Störungen bei körperlichen Beschwerden | A) Cognitive behavioral Therapy (CBT)  
B) supportive nondirective therapy (SNDT) | A total of 178 participants (62%) completed the 3-month intervention. Both psychotherapies resulted in significant reductions in total Children's Depression Rating Scale Revised score (37.3% for CBT and 31.9% for SNDT), but the difference between the 2 treatments was not significant (p = .16). There were large pre-post effect sizes for each treatment (d = 1.31 for CBT and d = 1.30 for SNDT). More than 65% of youth had a complete remission of depression at 3 months, with no difference between CBT and SNDT (67.8% and 63.2%, respectively). Compared to SNDT, CBT was associated with a greater reduction in IBD activity (p = .04) but no greater improvement on the Clinical Global Assessment Scale (p = .06) and health-related quality of life (IMPACT-III scale) (p = .07). |

<tr>
<td>Washington et al. 2001</td>
<td>55</td>
<td>Abhängigkeit/Missbrauch</td>
<td>A) cognitive therapy (24) B) experiential therapy (17) C) control group (14)</td>
<td>This experimental study examined effectiveness of two group therapy models on chemically dependent women's perceptions of self-efficacy and personal control. Participants were randomly assigned to two therapeutic approaches (experiential or cognitive) or the control group. Experimental and control groups were pre- and posttested on self-efficacy and personal control. Significant differences were found for social self-efficacy, with the cognitive and experiential groups having higher scores than the control group. Changes from pre- to posttest in social self-efficacy were greatest for the cognitive group. This study indicated that additional brief therapeutic interventions beyond those generally offered in drug rehabilitation programs are modestly useful.</td>

<tr>
<td>Köhnicht et al. 2013</td>
<td>31</td>
<td>Depressionen</td>
<td>A) Body psychotherapy (BPT) B) Waitlist control group</td>
<td>Thirty-one patients were included and twenty-one received the intervention. At the end of treatment patients in the immediate BPT group had significantly lower depressive symptom scores than the waiting group (mean difference 8.7, 95% confidence interval 1.0–16.7). Secondary outcomes did not show statistically significant differences. When the scores of the waiting group before and after BPT (as offered after the waiting period) were also considered in the analysis, the differences with the initial waiting group remained significant.</td>
